Adherence to Antiretroviral Therapy in Children and Adolescents Living with HIV  

(Last updated April 7, 2021; last reviewed April 7, 2021)

Panel’s Recommendations

- Strategies to maximize adherence should be discussed before and/or at initiation of antiretroviral therapy (ART) and again before changing regimens (AIII).
- Adherence to therapy must be assessed and promoted at each visit, and strategies to maintain and/or improve adherence must be continually explored (AIII).
- In addition to viral load monitoring, at least one other method of measuring adherence to ART should be used (AIII).
- Once-daily antiretroviral regimens and regimens with a low pill burden should be prescribed whenever feasible (AII*).

Rating of Recommendations: A = Strong; B = Moderate; C = Optional

Rating of Evidence: I = One or more randomized trials in children† with clinical outcomes and/or validated endpoints; I* = One or more randomized trials in adults with clinical outcomes and/or validated laboratory endpoints with accompanying data in children† from one or more well-designed, nonrandomized trials or observational cohort studies with long-term clinical outcomes; II = One or more well-designed, nonrandomized trials or observational cohort studies in children† with long-term outcomes; II* = One or more well-designed, nonrandomized trials or observational studies in adults with long-term clinical outcomes with accompanying data in children† from one or more similar nonrandomized trials or cohort studies with clinical outcome data; III = Expert opinion

†Studies that include children or children/adolescents, but not studies limited to post-pubertal adolescents

Background

Adherence to antiretroviral therapy (ART) is a principal determinant of virologic suppression. Suboptimal adherence may include missed or late doses, treatment interruptions and discontinuations, and subtherapeutic or partial dosing. Poor adherence will result in subtherapeutic plasma antiretroviral (ARV) drug concentrations, facilitating the development of resistance to one or more drugs in a given regimen and possible cross-resistance to other drugs in the same class. Multiple factors (including regimen potency, pharmacokinetics, drug interactions, viral fitness, and the genetic barrier to ARV resistance) influence the adherence-resistance relationship. In addition to compromising the efficacy of the current regimen, suboptimal adherence can limit the options for future effective drug regimens in patients who develop multidrug-resistant HIV; it can also increase the risk of secondary transmission of drug-resistant virus.

Poor adherence to ARV drugs is commonly encountered in the treatment of children and adolescents with HIV. A variety of factors—including medication formulation, frequency of dosing, drug toxicities and side effects, before child’s age and developmental stage, as well as psychosocial, behavioral, and sociodemographic characteristics of children and caregivers—have been associated with nonadherence. However, no consistent predictors of either good or poor adherence in children have been identified. Several studies have demonstrated that adherence is not static and can vary with time on treatment. More recently, findings from the U.S. Pediatric HIV/AIDS Cohort Study (PHACS) demonstrated that the prevalence of nonadherence increased with age. Among 381 children and adolescents with perinatal HIV infection, the prevalence of nonadherence increased from 31% to 50% ($P < 0.001$) and the prevalence of unsuppressed viral loads increased from 16% to 40% ($P < 0.001$) between pre-adolescence and late adolescence/young adulthood. Similarly, in a report from the Early Pediatric Initiation Canada Cure Cohort, only 73% of the children initiated on ART maintained viral suppression 3 years after it was first achieved. These findings illustrate the difficulty of maintaining high levels of adherence and underscore the need to work with patients and their families to ensure that adherence education, support, and assessment are integral components of care.

Specific Adherence Issues in Children

Adherence is a complex health behavior that is influenced by drug regimen, patient and family factors, and the patient-provider relationship. Despite improvements over the last several years, the availability of
once-daily and single-tablet regimens and palatable formulations for infants and young children is limited.\textsuperscript{12} Furthermore, infants and children are dependent on others for medication administration; adult caregivers may face barriers that contribute to nonadherence in children, including forgetting doses, changes in routine, being too busy, and child refusal.\textsuperscript{13,14} Some caregivers may place too much responsibility for managing medications on older children and adolescents before they are developmentally able to undertake such tasks.\textsuperscript{14} Adherence also may be jeopardized by social and health issues within a family (e.g., substance use, poor physical or mental health, unstable housing, poverty, violence, involvement with the criminal justice system, limited social support).\textsuperscript{16,17}

\textbf{Adherence Assessment and Monitoring}

Clinicians should begin assessing potential barriers to adherence and discussing the importance of adherence with patients before initiating or changing an ARV regimen. Evaluations should assess social and behavioral factors that may influence adherence and should identify individual needs for intervention. Clinicians should ask patients about their experience with taking medications, as well as concerns and expectations about treatment. Before beginning treatment, it is important that the patient explicitly agree to the treatment plan, which should include strategies to support adherence. It is also important to alert patients to potential adverse effects of ARV drugs (e.g., nausea, headaches, abdominal discomfort, sleep disturbances), explain how they can be managed, and emphasize the importance of informing the clinical team if they occur.

A routine adherence assessment should be incorporated into every clinic visit. Adherence is difficult to assess accurately; different methods of assessment have yielded different results, and each approach has limitations.\textsuperscript{18-20} Viral load monitoring is the most useful indicator of adherence and is a routine component of monitoring individuals who are on ART (see Plasma HIV-1 RNA [Viral Load] and CD4 Count Monitoring in the Adult and Adolescent Antiretroviral Guidelines). In addition, it can be used as positive reinforcement to encourage continued adherence.\textsuperscript{21} Clinicians should use at least one other method to assess adherence in addition to monitoring viral load.\textsuperscript{19} Table 13 includes common approaches to monitoring medication adherence.

\textbf{Strategies to Improve and Support Adherence}

When concerns about adherence emerge, a patient should be seen and/or contacted frequently (by telephone, text message, email, and social networking, as allowed within the context of local legal and regulatory requirements) to assess adherence and to determine the need for strategies that can improve and support adherence. During the first month of treatment (or a regimen change), a patient can be contacted weekly, or even daily, if necessary. The growing use of telemedicine visits, which allow remote and often face-to-face contact, provides new opportunities to support families and to visualize ART handling/swallowing and conduct directly observed therapy in the home setting, see Clinical and Laboratory Monitoring of Pediatric HIV Infection and Table 3.

Strategies should include simplifying the drug regimen, developing treatment plans that integrate medication administration into daily routines (e.g., associating medication administration with daily activities such as brushing teeth), and optimizing the use of social and community support services. Multifaceted approaches that include regimen-related strategies; educational, behavioral, and supportive strategies focused on children and families; and strategies that focus on health care providers may be more effective than one specific intervention. Table 14 below summarizes some of the strategies that can be used to support and improve adherence to ARV medications. The Centers for Disease Control and Prevention (CDC) offers a web-based toolkit (consisting of four evidence-based HIV medication adherence strategies) to HIV care providers.\textsuperscript{22}

\textbf{Regimen-Related Strategies}

To the extent possible, regimens should be simplified with respect to the number of pills or volume of liquid prescribed, as well as the number of daily doses, and drugs in the regimen should be chosen to minimize drug interactions and adverse effects (AEs).\textsuperscript{23} Efforts should be made to reduce the pill burden and pill size and to prescribe once-daily ARV regimens and single-tablet regimens whenever feasible (see Table 16 in Management of Children Receiving Antiretroviral Therapy). With the introduction of new drug classes and a wider array of
once-daily formulations, including some medications that are now available in a small pill size, more options
for less toxic, simplified regimens are now available, particularly for older children and adolescents. Several
studies in adults have demonstrated better adherence with once-daily ARV regimens than with twice-daily
regimens, and better adherence with single-tablet formulations than with multiple-tablet regimens.12,24–27
Appendix A, Table 1 shows which ARV drugs are available in fixed-dose combination (FDC) tablets, and
Appendix A, Table 2 provides information about minimum body weight requirements and other considerations
when using FDC tablets in children.

When nonadherence is related to the poor palatability of a liquid formulation or crushed pills, the offending
taste can sometimes be masked with a small amount of flavoring syrup or food if simultaneous administration
of food is not contraindicated (see Appendix A: Pediatric Antiretroviral Drug Information).28 Unfortunately,
the taste of lopinavir/ritonavir cannot be masked with flavoring syrup. A small study of children and youth
aged 4 years to 21 years found that training children to swallow pills was associated with improved adherence
at 6 months post-training.29 Finally, if drug-specific toxicities are thought to be contributing to nonadherence,
efforts should be made to alleviate the AEs by changing the particular drug (or, if necessary, the drug regimen)
when feasible.

**Patient/Family-Related Strategies**

Patient and caregiver education is an essential component of establishing good medication adherence in
children. Educating families about adherence should begin before initiating or changing ARV medications and
should include a discussion of the goals of therapy, the importance of optimizing adherence, and the specific
plans for supporting and maintaining a child’s medication adherence. Caregiver adherence education strategies
should include the provision of both information and adherence tools, such as written and visual materials;
a daily schedule illustrating times and doses of medications; and demonstration of the use of syringes,
medication cups, and pillboxes. Additionally, it may be helpful to assess the medication adherence of the
caregiver or other household members who currently take ARV drugs or other chronic medications.

Several behavioral tools can be used to integrate taking medications into a child’s daily routine. The use of
behavior modification techniques, especially the application of positive reinforcements and the use of small
incentives (including financial incentives) for taking medications, can be effective tools to promote adherence.30
Treating mental health disorders (e.g., depression) may facilitate adherence to complex ARV regimens.31,32

If the child has not been informed of their HIV status, HIV disclosure should be discussed with the caregivers.
In a recent review that explored the relationship between ART adherence and disclosure, five studies linked
disclosure to improved adherence, four studies found that disclosure led to worse adherence among study
participants, and five studies found no association.33 Therefore, the decision to disclose HIV status should
not necessarily be expected to improve adherence. The decision should instead be based on a comprehensive
assessment of the psychosocial milieu and the needs of the child and family.

In poorly adherent children who are at risk of disease progression and who have severe and persistent aversion
to taking medications, the use of a gastrostomy tube may be considered.34 If adequate resources are available,
home-nursing interventions or directly observed therapy (DOT) may also be beneficial. The evidence is mixed
as to the efficacy of programs that are designed to improve adherence through DOT, but DOT may still be a
useful strategy for some patients.35-37

Other strategies to support adherence include using mobile applications (apps) that remind patients to take
medications; setting patients’ cell phone alarms to go off at medication times; sending text-message reminders;
conducting motivational interviews; providing pill boxes, blister packaging, and other adherence support tools;
and delivering medications to the home. The CDC has an adherence toolbox, which includes a free mobile app
(CDC’s Every Dose Every Day mobile app) that is available through their website.

Several systematic reviews have been published evaluating the use of mobile phone technologies to improve
ART adherence (mHealth). A recent review by Demena and colleagues found what they described as “ambiguous
results with high variability” about the effectiveness of mobile phone-assisted mHealth interventions to improve
adherence in low- and middle-income countries. Of 17 studies, 56% reported a statistically significant positive impact of mHealth on adherence; 44% reported insignificant results. Another systematic review reported that the efficacy of mobile short message service (SMS) interventions varied depending on the specific SMS intervention tested. A third systematic review of the effectiveness of using mobile phone interventions to improve adherence to ART also reported mixed results; effectiveness varied depending on the measured outcomes and the specific intervention (e.g., whether the study evaluated the use of texts or the use of phone calls). It should be noted, however, that the evidence base for effective adherence interventions in adolescents and young adults who are taking daily ART is limited.

Two recently published studies provided evidence of the efficacy of peer-based interventions to improve adherence and viral suppression among adolescents and young people living with HIV in Africa. In Project YES! in Ndola, Zambia, 273 youth aged 15–24 years receiving HIV care in four health facilities—including a children’s hospital—were randomly assigned to monthly meetings with youth peer mentors. At 6 months, viral suppression improved in both study arms, but among participants in care at the pediatric clinic, the rate of viral suppression increased from 37.5% to 70.5% in the intervention arm versus the comparison, 60.3% to 59.4% (interaction term odds ratio [OR], 4.66; 95% confidence interval [CI], 1.84–11.78). Mavhu and colleagues tested the efficacy of a peer-led differentiated service delivery intervention on HIV clinical outcomes among adolescents, aged 13–19 years, with HIV in rural Zimbabwe. Sixteen clinics were randomized to standard of care or the enhanced intervention in which adolescents were assigned a community adolescent treatment supporter; attended monthly support group; and received text messages, calls, home visits, and clinic-based counseling. Overall 212 adolescents were recruited at intervention sites and 284 at control sites, median age 15 years. At 96 weeks, among 479 with data, 52 (25%) adolescents in the intervention arm versus 97 (36%) in the control had viral load >1000 copies/mL or died (adjusted prevalence ratio 0.58, 95% CI, 0.36–0.94; \( P = 0.03 \)). The study reported 28 deaths (17 in the intervention group, 11 in the control) and 57 hospital admissions (20 in the Zvandiri intervention group, 37 in the control group). These studies demonstrate that peer-based interventions have the potential to improve adherence and health outcomes among youth with HIV.

**Health Care Provider-Related Strategies**

To improve and support adherence, providers should maintain a nonjudgmental attitude, establish trust with patients and caregivers, and identify mutually acceptable goals for care. Providers can improve adherence through their relationships with patients’ families. This process begins early in a provider’s relationship with a family, when the clinician obtains explicit agreement about the medication and treatment plan and any further strategies to support adherence. Fostering a trusting relationship and engaging in open communication are particularly important. Provider characteristics that have been associated with improved patient adherence in adults include consistency, willingness to give information and ask questions, technical expertise, and commitment to follow-up. Creating an environment in the health care setting that is child-centered and includes caregivers in adherence support also has been shown to improve treatment outcomes. Immigrant children and families may face unique social and cultural issues; it is important to recognize these issues and facilitate establishing links to community resources, particularly for families who are recent immigrants. Providing comprehensive multidisciplinary care (e.g., with nurses, case managers, pharmacists, social workers, psychiatric care providers) also may better serve more complex patient and family needs, including adherence. Provider-initiated education about viral load and counseling targeted to viral load results and the health benefits of undetectable viral load is another strategy providers can use.
### Table 13. Approaches for Monitoring Medication Adherence

<table>
<thead>
<tr>
<th>Routine Assessment of Medication Adherence in Clinical Care&lt;sup&gt;a&lt;/sup&gt;</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monitor viral load.</td>
<td>Viral load monitoring should be done more frequently after initiating or changing medications.&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td>Assess a quantitative self-report of missed doses.</td>
<td>Ask the patient and/or caregiver about the number of missed doses over a defined period (1, 3, or 7 days).</td>
</tr>
<tr>
<td>Request a description of the medication regimen.</td>
<td>Ask the patient and/or caregiver about the name, appearance, and number of medications, and how often the medications are taken.</td>
</tr>
<tr>
<td>Assess barriers to medication administration.</td>
<td>Engage the patient and caregiver in a dialogue about potential barriers to adherence and strategies to overcome them.</td>
</tr>
<tr>
<td>Monitor pharmacy refills.</td>
<td>Approaches include a pharmacy-based or clinic-based assessment of on-time medication refills.</td>
</tr>
<tr>
<td>Employ telemedicine to monitor and support medication administration.</td>
<td>Telemedicine visits allow remote and often face-to-face contact and provide new opportunities to support families; to visualize ART preparation, handling, and swallowing; and to conduct DOT in the home setting.</td>
</tr>
<tr>
<td>Conduct announced and unannounced pill counts.</td>
<td>Approaches include asking patients to bring medications to the clinic, home visits, or providing referral to community health nursing.</td>
</tr>
</tbody>
</table>

<table>

Table 14. Strategies to Improve Adherence to Antiretroviral Medications

<table>
<thead>
<tr>
<th>Initial Intervention Strategies</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Establish trust and identify mutually acceptable goals for care.</td>
</tr>
<tr>
<td>• Obtain explicit agreement on the need for treatment and adherence.</td>
</tr>
<tr>
<td>• Identify depression, low self-esteem, substance abuse, or other mental health issues in the child/adolescent and/or the caregiver that may affect adherence. Evaluate and initiate treatment for mental health issues before starting ARV drugs, if possible.</td>
</tr>
<tr>
<td>• Determine whether the child is aware of their HIV status. Consider talking to the child’s caregivers about disclosing this information to the child in a developmentally appropriate way.</td>
</tr>
<tr>
<td>• Identify family, friends, health team members, and others who can support adherence.</td>
</tr>
<tr>
<td>• Educate the patient and family about the critical role of adherence in therapy outcome, including the relationship between partial adherence and resistance and the potential impact on future drug regimen choices. Develop a treatment plan that the patient and family understand and to which they feel committed.</td>
</tr>
<tr>
<td>• Work with the patient and family to make specific plans for taking medications as prescribed and for supporting adherence. Assist them in arranging administration during day care, school, and in other settings, when needed. Consider home delivery of medications.</td>
</tr>
<tr>
<td>• Establish a patient’s readiness to take medication by staging practice sessions or by other means.</td>
</tr>
<tr>
<td>• Schedule a home visit or telemedicine visit to review medications and determine how they will be administered in the home setting.</td>
</tr>
<tr>
<td>• In certain circumstances, consider a brief period of hospitalization at the start of therapy for patient education and to assess the tolerability of the chosen medications.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Medication Strategies</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Choose the simplest regimen possible; reduce dosing frequency, pill size, and number of pills (see Appendix A, Table 1 and Appendix A, Table 2).</td>
</tr>
<tr>
<td>• When choosing a regimen, consider the patient’s daily and weekly routines and potential variations in patient and family activities.</td>
</tr>
<tr>
<td>• Choose the most palatable medicine possible (pharmacists may be able to add syrups or flavoring agents to increase palatability).</td>
</tr>
<tr>
<td>• Choose drugs with the fewest AEs; provide anticipatory guidance for managing AEs.</td>
</tr>
<tr>
<td>• Simplify food requirements for medication administration.</td>
</tr>
<tr>
<td>• Prescribe drugs carefully to avoid adverse drug-drug interactions.</td>
</tr>
<tr>
<td>• Assess pill-swallowing capacity and offer pill-swallowing training and aids (e.g., pill-swallowing cup, pill glide). Adjust pill size as needed.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Follow-Up Intervention Strategies</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Have more than one member of the multidisciplinary team monitor adherence at each visit and in between visits by telephone, email, text, and social media, as needed.</td>
</tr>
<tr>
<td>• Provide ongoing support, encouragement, and understanding of the difficulties associated with maintaining adherence to daily medication regimens.</td>
</tr>
<tr>
<td>• Provide education and counseling that explain the meaning and significance of viral load results.</td>
</tr>
<tr>
<td>• Use patient education aids, including pictures, calendars, and stickers.</td>
</tr>
<tr>
<td>• Encourage the use of pill boxes, reminders, mobile apps, alarms, and timers.</td>
</tr>
<tr>
<td>• Provide follow-up clinic visits, telephone calls, text messages and telemedicine visits to support and assess adherence.</td>
</tr>
<tr>
<td>• Provide access to support groups, peer groups, or one-on-one counseling for caregivers and patients, especially for those with known depression or drug use issues that are known to decrease adherence.</td>
</tr>
<tr>
<td>• Provide pharmacist-based adherence support, such as medication education and counseling, blister packs, refill reminders, automatic refills, and home delivery of medications.</td>
</tr>
<tr>
<td>• Consider DOT at home, in the clinic, or, in certain circumstances, during a brief period of inpatient hospitalization.</td>
</tr>
<tr>
<td>• Consider gastrostomy tube use in certain circumstances.</td>
</tr>
<tr>
<td>• Information on other interventions to consider can be found at the Complete Listing of Medication Adherence Evidence-Based Behavioral Interventions on CDC’s website.</td>
</tr>
<tr>
<td>• Consult the CDC Every Dose Every Day toolkit.</td>
</tr>
</tbody>
</table>
